

The Ultimate "No-Brainer" Setup Guide

Get your Instagram & Pinterest Downloader Bot Running From Scratch

Hey! Don't worry if you've never touched code or run a bot before. This guide is written specifically to take you from **absolute zero** to a perfectly running automated media downloader bot. Just follow these simple steps step-by-step.

PART 1: Installing Python (The Engine)

Python is the programming language that runs your bot. Let's install it correctly.

1. Go to the official website: python.org/downloads.
2. Click the big yellow **Download Python 3.x.x** button (whatever the latest version is).
3. Open the downloaded installer file.
4. **CRITICAL STEP (DO NOT MISS THIS):** At the very bottom of the first setup window, look for a checkbox that says "**Add python.exe to PATH**".

☒ **CHECK THAT BOX!** If you don't check it, your computer won't know how to run the bot.

5. Click **Install Now** and wait for it to finish.

PART 2: Setting Up Your Bot Folder

As shown in your file manager screenshot, all your files must live happily together in one single folder.

- Create a folder on your computer named something clean like **MediaBot**.
- Place your **bot.py** file and **proxies.txt** file inside this folder.
- Make sure your **ffmpeg.exe** is placed inside this exact same folder too, as shown in your layout picture! This gives your bot superpower GPU rendering capabilities.

PART 3: Installing the Modules (The Fuel)

The bot relies on a few external libraries to talk to Telegram and download media. Let's install them all at once.

1. Hold the **Windows Key** and press **R** on your keyboard.
2. Type **cmd** and press **Enter**. A black window (Command Prompt) will pop up.
3. Copy and paste the following line into that window, then press **Enter**:

```
pip install pyTelegramBotAPI yt-dlp instaloader colorama Pillow
```

Wait until it says "Successfully installed". If you get an error saying 'pip' is not recognized, go back to Part 1—you forgot to check the "Add to PATH" box!

PART 4: Getting Your Telegram Bot Token

Your code currently has a token built-in, but if you ever need your own fresh identity:

1. Open Telegram and search for **@BotFather** (the official verified bot creator).
2. Send the command: **/newbot**
3. Follow its instructions to give your bot a name and a username.
4. BotFather will give you a long string of numbers and letters called an **API Token**. Keep this secret!

PART 5: How to Run the Bot

To start your bot without writing terminal commands every time, you can use the **RUN.bat** file shown in your project folder:

How to create the RUN.bat file:

1. Right-click inside your bot folder, select **New** → **Text Document**.
2. Name it **RUN.bat** (make sure to delete the **.txt** extension from the end).
3. Right-click **RUN.bat**, select **Edit** (or Open with Notepad), paste these two lines, and save:

```
@echo off
python bot.py
pause
```

Now, simply **double-click RUN.bat** anytime you want your bot alive! A command window will open showing [LIVE] status messages.

PART 6: 🍪 Optional but Highly Recommended: Adding Instagram Cookies

Instagram hates automation and will eventually block your bot if it downloads too many reels. To fix this, you feed it your browser cookies:

1. Install a free browser extension like **"Get COOKIES.TXT LOCALLY"** or **"EditThisCookie"** on Chrome/Edge/Firefox.
2. Go to **instagram.com** on your browser and log into a secondary backup account (never use your main account, just in case!).

3. Click the extension icon and select **Export / Download as cookies.txt**.
4. Move that downloaded `cookies.txt` file straight into your main bot folder next to `bot.py`. Your bot will automatically find it and bypass restrictions like a pro!
